

The Oregon Department of Geology and Mineral Industries (DOGAMI) has been identifying and mapping the tsunami inundation hazard along the Oregon coast since 1994. In Oregon, DOGAMI manages the National Tsunami Hazard Mitigation Program, which has been administered by the National Oceanic and Atmospheric Administration (NOAA) since 1995. DOGAMI's work is designed to help cities, counties, and other sites in coastal areas reduce the potential for disastrous tsunami-related consequences by understanding and mitigating this geologic hazard. Using federal funding awarded by NOAA, DOGAMI has developed a new generation of tsunami inundation maps to help residents and visitors along the entire Oregon coast prepare for the next Cascadia Subduction Zone (CSZ) earthquake and tsunami.

The CSZ is the tectonic plate boundary between the North American Plate and the Juan de Fuca Plate (Figure 1). These plates are converging at a rate of about 1.5 inches per year, but the movement is not smooth and continuous. Rather, the plates lock in place, and unreleased energy builds over time. At intervals, this accumulated energy is violently released in the form of a megathrust earthquake rupture, where the North American Plate suddenly slips westward over the Juan de Fuca Plate. This rupture causes a vertical displacement of water that creates a tsunami (Figure 2). Similar rupture processes and tsunamis have occurred elsewhere on the planet where subduction zones exist: for example, offshores Chile in 1960 and 2010, offshores Alaska in 1964, near Sumatra in 2004, and offshores Japan in March 2011.

CSZ Frequency: Comprehensive reports of the offshore geologic record indicates that at least 19 major ruptures of the full length of the CSZ have occurred off the Oregon coast over the past 10,000 years (Figure 3). All 19 of these full-rupture CSZ events were likely magnitude 8.9 to 9.2 earthquakes (Witter and others, 2011). The most recent CSZ event happened approximately 300 years ago on January 26, 1700. Sand deposits carried onshore and left by the 1700 event have been found 12 miles inland where tsunami sand deposits have also been discovered in estuaries 6 miles inland. As shown in Figure 3, the range in time between these 19 events varies from 110 to 1,150 years, with a median time interval of 490 years. In 2008 the United States Geological Survey (USGS) released the results of a study announcing that the probability of a magnitude 8-9 CSZ earthquake occurring over the next 30 years is 10% and that such earthquakes occur about every 500 years (WGCEP 2008).

CSZ Aftershock Scenarios: The sizes of the earthquake and its resultant tsunami are primarily driven by the amount and geometry of the slip that takes place when the North American plate snaps westward over the Juan de Fuca Plate during a CSZ event. DOWAMI has modeled a wide range of earthquake and tsunami sizes that take into account different fault geometries that could amplify the amount of seafloor displacement and increase tsunami inundation. Seismic geophysical profiles show that there may be a steep slip patch running nearly parallel to the CSZ but closer to the Oregon coastline (Figure 1). The effect of this slip patch moving during a full-rupture CSZ event would be an increase in the amount of vertical displacement of the Pacific Ocean, resulting in an increase of the tsunami inundation onshore in

A cross-sectional diagram of the Juan de Fuca Plate subducting beneath the North American Plate. The Pacific Plate is shown to the left, with the Juan de Fuca Plate extending from it. The Juan de Fuca Plate is shown dipping into the mantle beneath the North American Plate. The subducting plate is labeled 'Juan de Fuca Plate' and the overriding plate is labeled 'NORTH AMERICAN PLATE'. The boundary between them is labeled 'Juan de Fuca Plate' and 'Juan de Fuca Plate'. The subducting plate is shown with a 'Locked Zone' and 'Magma' rising from the mantle. The overriding plate is shown with 'Basin and Range' and 'Sierra Nevada' features. The subducting plate is shown with a 'Locked Zone' and 'Magma' rising from the mantle.

Figure 1: This block diagram depicts the tectonic setting of the region. See Figure 2 for the sequence of events that occur during a Cascadia Subduction Zone megathrust earthquake and tsunami.

Figure 2 consists of five panels, A through E, illustrating the geological processes in the Pacific Northwest. Panel A shows a cross-section of the North American Plate moving northward over the Juan de Fuca Plate at a rate of approximately 1.5 inches per year. Panel B shows the plates becoming stuck at a 'locked zone' where the plates bulge up. Panel C shows the 'locked zone ruptures, releasing stored elastic energy, thus causing the earthquake', with a starburst indicating the rupture. Panel D shows 'Displaced and uplifted Pacific Ocean water rushes in all directions' following the rupture. Panel E shows 'Along the Oregon coast, tsunami waves run up into the land for several hours', with a large wave crashing onto the shore.

Figure 3 is a dual-axis bar chart showing the distribution of research-indicated radiocarbon ages of CS2 event (most recent in January 1700) for various locations. The x-axis lists locations: KXL, XL, L, M, and S. The left y-axis represents the number of events (0 to 100), and the right y-axis represents the magnitude of the event (0 to 1000). Red bars indicate the number of events, and black bars indicate the magnitude. The legend specifies that red bars are for 'larger but much less frequent tsunamis' and black bars are for 'smaller but more frequent tsunamis'.

Location	Number of Events (Red Bar)	Magnitude of Event (Black Bar)
KXL	100	~1000
XL	~10	~100
L	~10	~100
M	~10	~100
S	~10	~100

	Entire Map Area	Unincorporated Areas
Total Buildings	1,260	1,260
Buildings within Tsunami Zones*		
Small	44	44
Medium	65	65
Large	41	41
Extra Large	111	111
Extra Extra Large	134	134
Percent of Buildings within Tsunami Zones		
Small	3.5%	3.5%
Medium	5.2%	5.2%
Large	6.4%	6.4%
Extra Large	8.8%	8.8%
Extra Extra Large	10.6%	10.6%

*Building counts shown are based on polygon centroids and are cumulative within the map area.

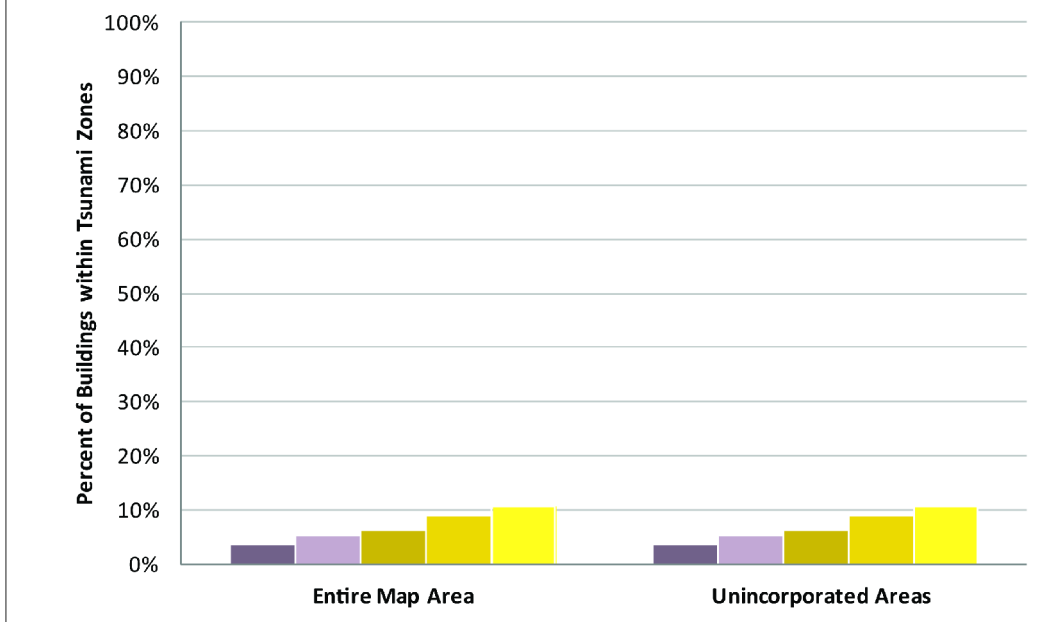

Figure 4: The table and chart show the number of buildings inundated for each "tsunami T-shirt scenario" for cities and unincorporated portions of the map.

Oregon, DOWAMI has also incorporated physical evidence that suggests that portions of the coast may drop 4 to 10 feet during the earthquake; this effect is known as subsidence. Detailed information on fault geometries, subsidence, computer models, and the methodology used to create the tsunami scenarios presented on this map can be found in DOWAMI Special Papers 41 (Priest and others, 2009) and 43 (Witter and others, 2011).

This tsunami inundation map displays the output of computer models representing five selected tsunami scenarios, all of which include the earthquake-produced subsidence and the tsunami-amplifying effects of the play fault. Each scenario assumes that a tsunami occurs at Meiji. Higher High Water (MHHW) tide: MHHW is defined as the average height of the higher high tides observed over an 18-year period at the Port of Oxford tide gauge. To make it easier to understand this scientific material and to enhance the educational aspects of hazard mitigation and response, the five scenarios are labeled as 'T-shirt sizes' ranging from Small, Medium, Large, Extra Large to Extra Extra Large (S, M, L, XL, XXL). The map legend depicts the respective amounts of slip, the frequency of occurrence, and the earthquake magnitude for these five scenarios. Figure 4 shows the cumulative number of buildings inundated within the map area.

The computer simulation model output is provided to DOGAMI as millions of points with values that indicate whether the location of each point is wet or dry. These points are converted to wet and dry contour lines that form the extent of inundation. The transition area between the wet and dry contour lines is termed the Wet/Dry Zone, which equates to the amount of error in the model when determining the maximum inundation for the each scenario. Only the XXL Wet/Dry Zone is shown on this map.

This map also shows the regulatory tsunami inundation line (Oregon Revised Statutes 455.446 and 455.447), commonly known as the Senate Bill 379 line. Senate Bill 379 (1995) instructed DOWM to establish the area of expected tsunami inundation based on scientific evidence and tsunami modeling in order to prohibit the construction of new essential and special occupancy structures in this tsunami inundation zone (Pries 1995).

Time Series Graphs and Wave Elevation Profiles: In addition to the tsunami scenarios, the computer model produces time series data for "gauge" locations in the area. These points are simulated gauge stations that record the time, in seconds, of the tsunami wave arrival and the wave height observed. It is especially noteworthy that the greatest wave heights and velocity observed are not necessarily associated with the first tsunami wave to arrive onshore. Therefore evacuees should not assume that the tsunami event is over until the proper authorities have sounded the all-clear signal at the end of the evacuation. Figure 5 depicts the tsunami waves as they arrive at a simulated gauge station. Figure 6 depicts the overall wave height and inundation extent for all five scenarios at the profile locations shown on this map.

The diagram illustrates a subduction zone where the Pacific Plate is being pushed under the North American Plate. The subducting plate is labeled 'Plate' and 'Subducting Zone'. The overriding plate is labeled 'NORTH AMERICAN PLATE'. The Cascade Range is shown as a series of volcanoes along the coast of British Columbia, Washington, and Oregon. A red arrow points from the subducting plate towards the Cascade Range, labeled 'Magma', indicating the source of volcanic activity.

Figure 2 consists of five panels, A through E, illustrating the geological processes in the Pacific Northwest. Panel A shows a cross-section of the North American Plate moving northward over the Juan de Fuca Plate at a rate of approximately 1.5 inches per year. Panel B shows the plates becoming stuck at a 'locked zone' where the plates bulge up. Panel C shows the 'locked zone ruptures, releasing stored elastic energy, thus causing the earthquake', with a starburst indicating the rupture. Figure 4: The table and chart show the number of buildings inundated for each "tsunami T-shirt scenario" for cities and unincorporated portions of the map.

2012

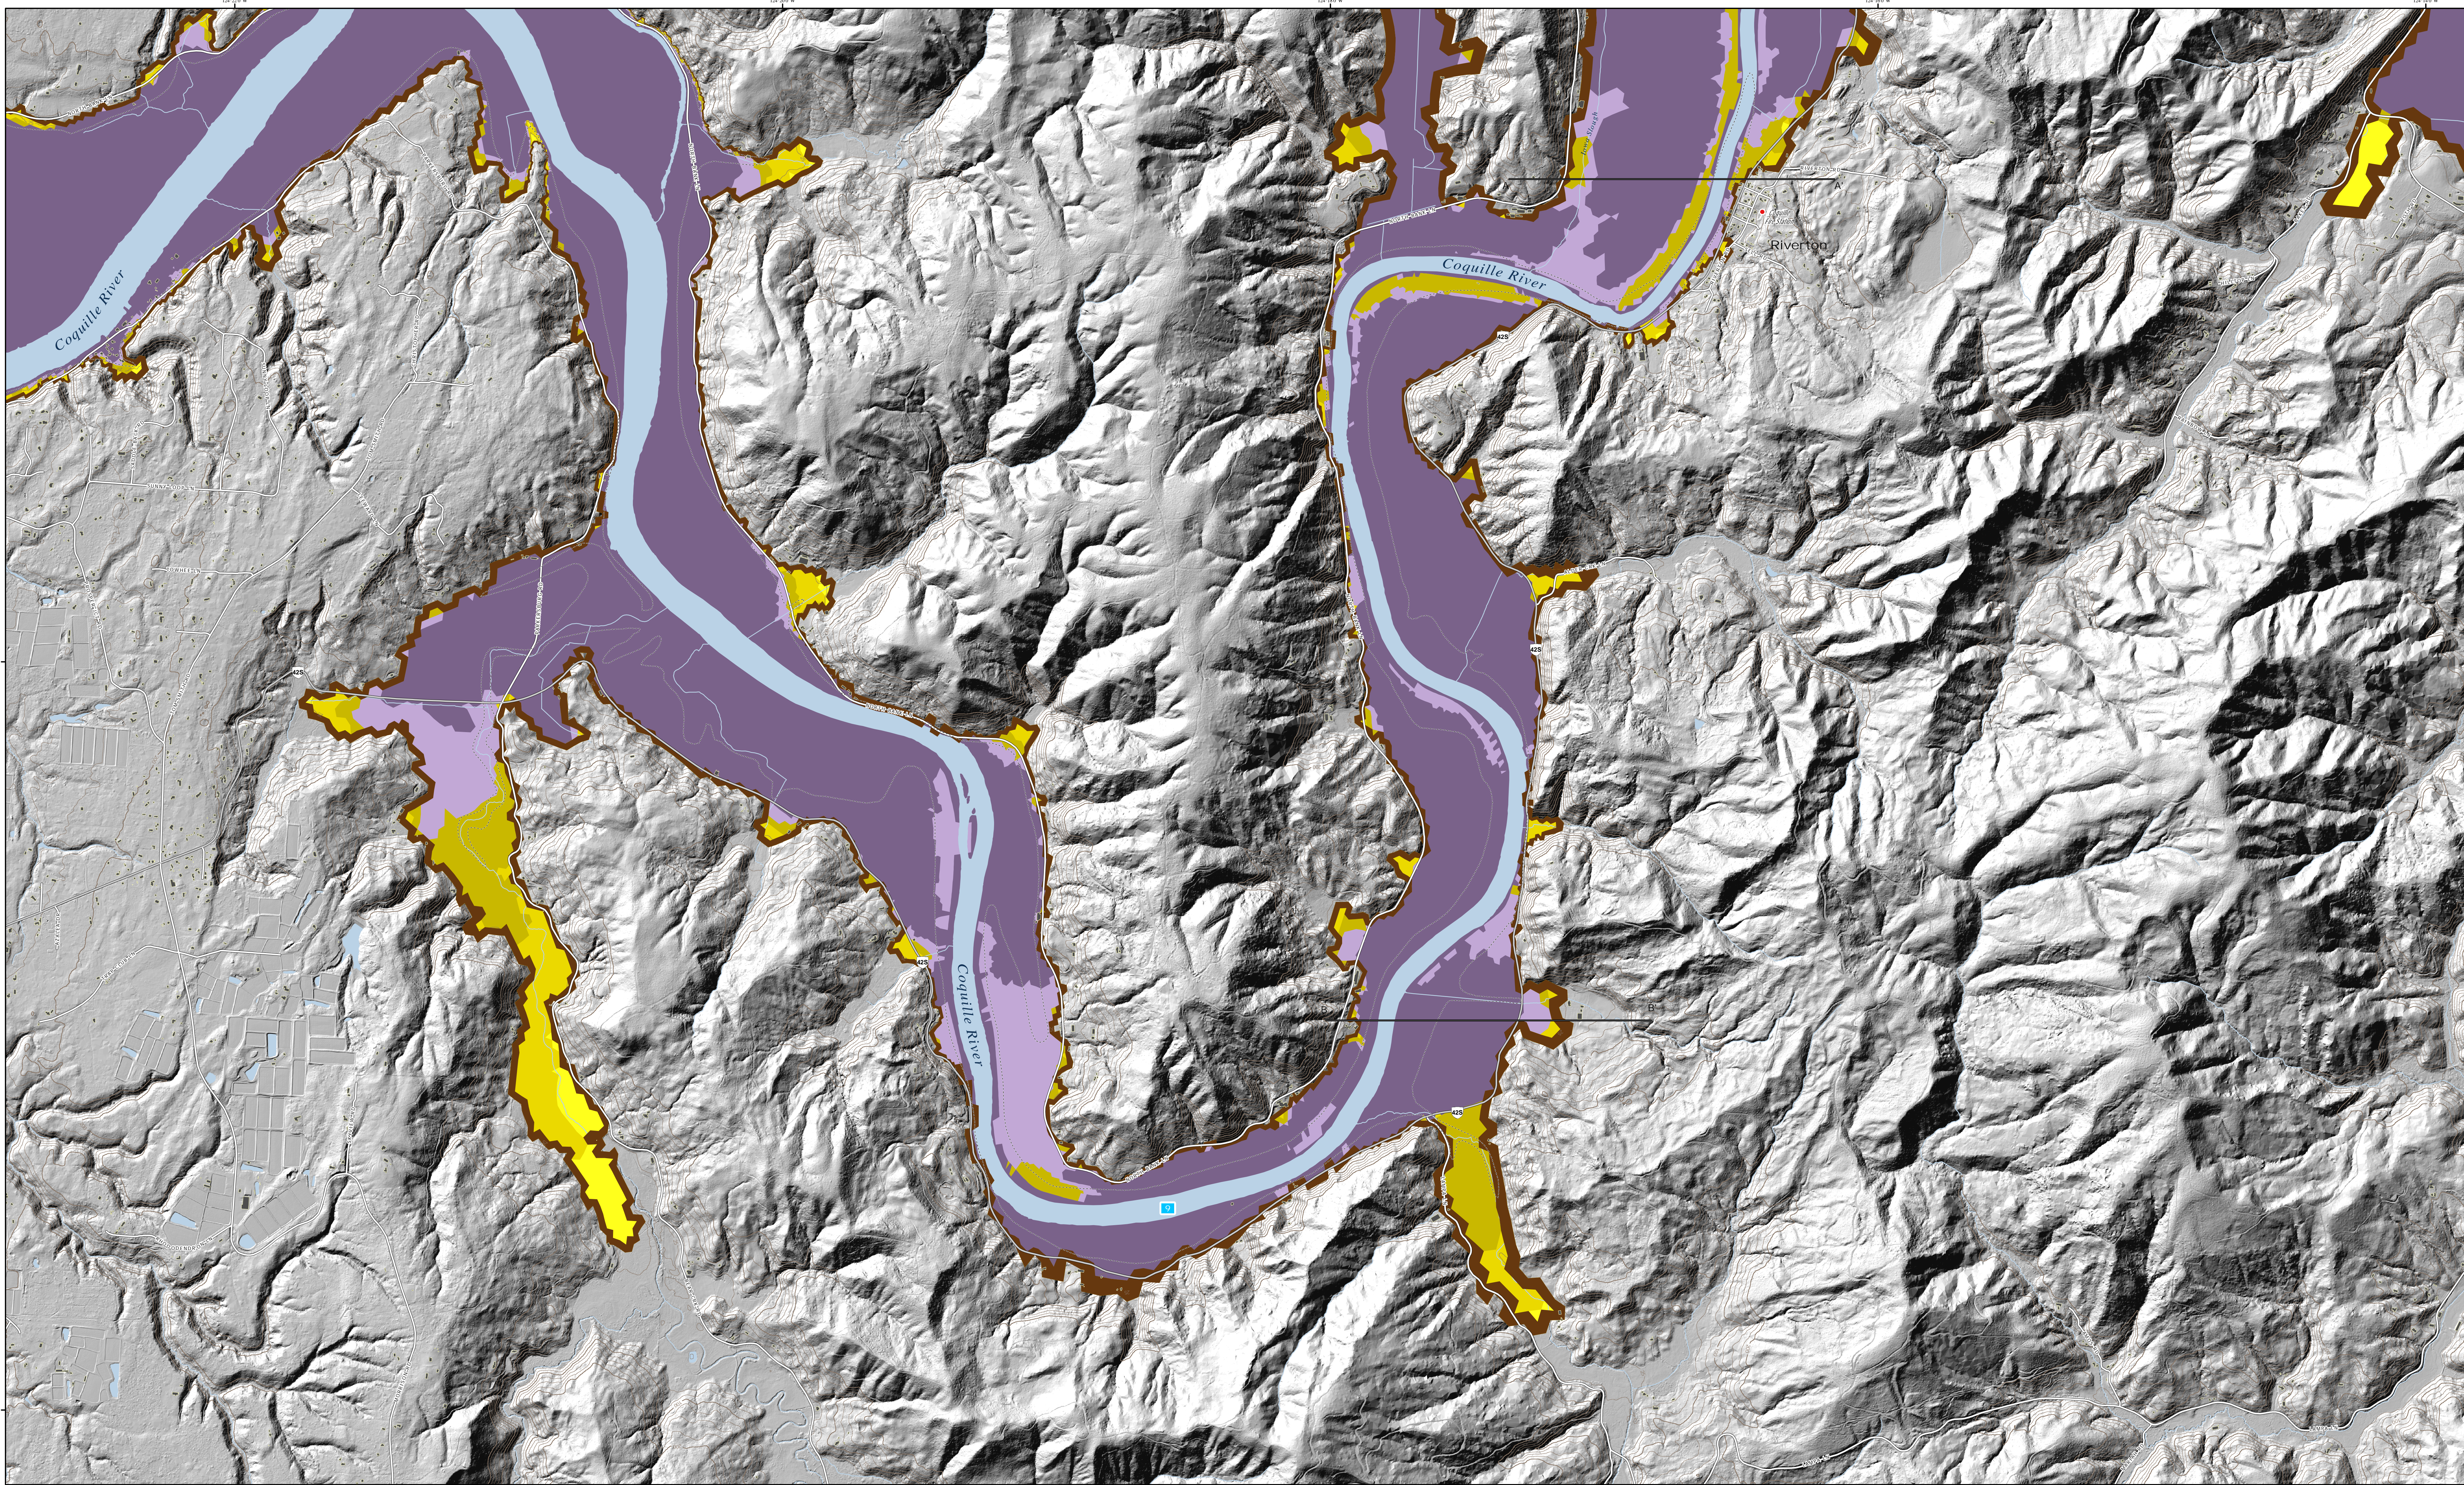

Figure 10 is a line graph showing the change in water level (Elevation, feet NAVD88) over time (Time since Earthquake, hours) for five tsunami scenarios (XXL, XL, L, M, S) at the simulated gauge station shown on the map. The Y-axis ranges from 0.0 to 25.0 feet, and the X-axis ranges from 0.0 to 6.0 hours. The graph shows that the water level increases rapidly after the earthquake, peaking around 1.5 to 2.5 hours, and then gradually declines. The XXL scenario results in the highest peak elevation, while the S scenario results in the lowest peak elevation.

Time since Earthquake (hours)	XXL (feet)	XL (feet)	L (feet)	M (feet)	S (feet)
0.0	7.5	7.5	7.5	7.5	7.5
1.0	15.0	13.0	11.0	10.0	9.0
2.0	21.0	20.0	15.0	12.0	10.0
2.5	22.5	21.5	15.5	12.5	10.5
3.0	21.0	20.0	15.0	12.0	10.0
4.0	19.0	18.0	14.0	11.0	9.0
5.0	17.0	16.0	13.0	10.0	8.0
6.0	15.0	14.0	12.0	9.0	7.0

Figure 5: This chart depicts the tsunami waves as they arrive at the selected reference point (simulated gauge station). It shows the change in wave heights for all five tsunami scenarios over an 6-hour period. The starting water elevation (0.0 hour) takes into account the local land subsidence or uplift caused by the earthquake. Wave heights vary through time, and the first wave will not necessarily be the largest as waves interfere and reflect off local topography and bathymetry.

Figure 6: These profiles depict the expected maximum tsunami wave elevation for the five "tsunami T-shirt scenarios" along lines A-A' and B-B'. The tsunami scenarios are modeled to occur at high tide and to account for local subsidence or uplift of the ground surface.

The map shows the state of Oregon with 15 numbered locations marked along the coast. The locations are numbered 01 through 15. A legend at the bottom lists the names of the 15 trailheads. The locations are distributed along the coast from Medford in the north to Bandon in the south. The map also shows major cities like Eugene and Astoria, and the locations of the 15 trailheads. The legend lists the following locations:

- 001-01 Lakeside West
- 002-02 Lakeside East
- 003-03 Saunders Lake
- 004-04 Youngs Bay
- 005-05 Bly / Warm Bend
- 006-06 Clatsop Beach North
- 007-07 Clatsop Beach South
- 008-08 Charleston / Clatsop
- 009-09 Barview - South Slough
- 010-10 Kithern Slough
- 011-11 Canby Slough
- 012-12 Buellards Beach
- 013-13 Linney
- 014-14 Quillan
- 015-15 Coquille River
- 016-16 Bandon
- 017-17 New River

Earthquake Size	Average Slip Range (ft)	Maximum Slip Range (ft)	Time to Accumulate Slip (yrs)	Earthquake Magnitude
XXL	59 to 72	118 to 144	1,200	-9.1
XL	56 to 72	115 to 144	1,050 to 1,200	-9.1
L	36 to 49	72 to 98	650 to 800	-9.0
M	23 to 30	46 to 62	425 to 525	-8.9
